## FORENOON SESSION DETAILS

### Image of session

The screenshot shows a SoloLearn mobile application interface. At the top, there's a blue header bar with the SoloLearn logo, a code icon, the text 'Basic Concepts', and 'What is C'. On the right side of the header are 'XP' and '0' (experience points) and a circular progress bar showing '1/1'. Below the header is a large white content area titled 'Introducing C'. The text explains that C is a general-purpose programming language used for various applications like operating systems and databases. A yellow callout box highlights that understanding computer memory is important for C. At the bottom of the content area, there are '962 COMMENTS' and a green circular button with a right-pointing arrow. On the left side of the content area, there's a dark gray sidebar with a back arrow and the text '© 2020 SoloLearn Inc.'

The screenshot shows a SoloLearn mobile application interface. At the top, there's a blue header bar with the SoloLearn logo, an infinity symbol icon, the text 'Conditionals and Loops', and 'Conditionals'. On the right side of the header are 'XP' and '36' (experience points) and a circular progress bar showing '1/4'. Below the header is a large white content area titled 'Conditionals'. The text explains that conditionals perform different computations or actions based on conditions. It then focuses on the 'if' statement, describing it as a conditional control structure that executes statements when an expression is true. It provides the syntax: 'if (expression) statements'. An example code block is shown: 

```
#include <stdio.h>
int main() {
    int score = 89;
    if (score < 75)
```

 At the bottom of the content area, there are '1/4' and a green circular button with a right-pointing arrow. On the left side of the content area, there's a dark gray sidebar with a back arrow and the text '© 2020 SoloLearn Inc.'

## Relational Operators

There are six **relational operators** that can be used to form a Boolean expression, which returns true or false:

- < less than
- <= less than or equal to
- > greater than
- >= greater than or equal to
- == equal to
- != not equal to

For example:

```
int num = 41;
num += 1;
if (num == 42) {
    printf("You won!");
}
```

[Try It Yourself](#)

## C Programming

by Thursday - 18/06/2020  
modules!

→ Basic Concepts .

> what is C

Introducing C

C is a general purpose programming language.  
It has been around for nearly 50 years. C has been used to write software from OS (including Windows & many others) to complex programs like Python interpreter, Oracle database & etc.

> Hello World !

#include <stdio.h>

int main()

{ printf ("Hello, world!\n");

return 0;

}

printf function

The printf function is used to generate output.

#include <stdio.h>

int main()

{ printf ("Hello, world!\n");

return 0;

}

> Data types

C supports the following basic data types:

int - integer , a whole no .

float - floating point, a no. with a decimal part  
double - double precision floating point value.

char : single character

> Variables

A variable is a name which can be identified.

The name of a variable (also called the identifier) must begin with either a letter or an underscore & can be composed of letters, digits & the underscore character.

> Constants

A constant is a value that cannot be changed from its initial assignment. By using constants with meaningful names, code is easier to read & understand. To distinguish constants from variables, a common practice is to use uppercase identifiers.

Another way to identify a constant is with the #define preprocessor directive. The #define directive uses宏来 define constant values.

> Input

• fgets() or number of ways of taking user input. gets() Returns the value of the next single character in input.

• The gets() function is used to read strings as defined. It requires a character, also called a string. A string is stored in a char array.

> Output

- Date: 1 /
- `putchar()` outputs a single character.
  - `putc()` function used to display output as a string.
  - `putf()` is added in a character array.
  - `scanf()` scans input that matches format specifier

#### Formatted Input:

The `scanf()` function is used to assign input to variables. A call to this function reads input according to format specifiers that convert input as necessary.

The `scanf()` statement reads input from matrix assignment.

#### Formatting Output:

The `printf` function was introduced in previous pit Hello World Program. A call to this function requires a format string which includes escape characters sequences for left padding, special characters, format specifiers that are replaced by values.

#### Comments:

- Comments are explanatory instructions that you can include in a program to help the reader of your code.
- Single-line comments: C++ introduced a double start comment // as a way to comment single line.

#### Arithmetic Operators:

- Support mathematical operations + (addition), - (subtraction), \* (multiplication), / (division), % (modulus division).
- Operator used forward in assignment statement.

#### Operator precedence:

- The + - are evaluated in precedence, one after the other.
- \*, /, % are evaluated left to right from left to right & then + - . etc in order, from left to right.

#### Type Conversion:

- When a numeric expression contains operators of different data types, they are automatically converted as necessary via a process called type conversion.

#### Assignment Operators:

- Evaluate the expression on the right side.
- the equal sign, first of other operand than value of the variable on the left side of the =.

#### Increment & Decrement:

- Increment operator ++, adding 1 to a variable.
- Decrement operator --, subtracting 1 from a variable.

#### Conditionals & loops:

- Conditionals are used to perform different computations in certain depending on whether a condition evaluates true or false.

#### The if statement:

- if (expression)  
  statements.

### \* Relational Operators.

< less than or equal to , > greater than,  
>= greater than or equal to , == equals, != not equals

### \* The if - else statement

This statement can include an optional else clause that executes statements when an expression is false

### \* Conditional Expressions

Another way to form a if - else statement is by using the ?: operator as a conditional expression

### > Used of Statements.

An if statement can include another if statement to form a nested statement. Nothing will follow a decision gate based on further requirements.

### \* The if - else if statements

When a decision among three or more actions is needed, the if - else if statement can be used. There can be multiple else clauses of the last else clause if optional.

### \* The switch statement

The switch statement handles program control by matching the result of an expression with a value. This can be multiple values with unique labels.

### > Logical Operators:

Logical operators || and || are used to form a compound decision or present them both multiple conditions. A third logical operator is used to reverse the state of Boolean expression.

### \* The || Operator.

The logical AND operator || returns a true result only when both expressions are true

### \* The || Operator.

The logical OR operator || returns a true result when any one expression is with the expression is true

### \* The ! Operator

The logical NOT operator ! makes a true value its inverse. If it's true, it becomes false, if not false becomes true.

### \* The while loop

while (expression) { Statement(s); }

### > The do - while loop

do { Statement;

    } while (expression);

### > break & continue

\* The break statement was introduced to use in switch statement. It's also useful for immediately exiting a loop.

\* The continue action is you want to skip with loop, but skip ahead to the next iteration, you use the continue statement.

### \* The for-loop

for (init value; condition; increment) { Statement }

#### AFTERNOON SESSION DETAILS

Image of session

**Screenshot 1: Variable Scope**

Functions, Arrays & Pointers  
Functions

XP 81 4/5

**Variable Scope**

Variable scope refers to the visibility of variables within a program. Variables declared in a function are **local** to that block of code and cannot be referred to outside the function. Variables declared outside all functions are **global** to the entire program. For example, constants declared with a `#define` at the top of a program are visible to the entire program.

The following program uses both **local** and **global** variables:

```
#include <stdio.h>
int global1 = 0;
int main() {
    int local1, local2;
    local1 = 5;
    local2 = 10;
    global1 = local1 + local2;
    printf("%d\n", global1); /* 15 */
    return 0;
}
```

**Screenshot 2: Static Variables**

Functions, Arrays & Pointers  
Functions

XP 81 5/5

**Static Variables**

Static variables have a local scope but are not destroyed when a function is exited. Therefore, a static variable retains its value for the life of the program and can be accessed every time the function is re-entered.

A static variable is initialized when declared and requires the prefix `static`.

The following program uses a static variable:

```
#include <stdio.h>
void say_hello();
int main() {
    int i;
    for (i = 0; i < 5; i++) {
        say_hello();
    }
    return 0;
}
void say_hello() {
```

**Screenshot 3: Pointers and Arrays**

Functions, Arrays & Pointers  
More On Pointers

XP 87 1/3

**Pointers and Arrays**

Pointers are especially useful with arrays. An `array` declaration reserves a block of contiguous memory addresses for its elements. With pointers, we can point to the first element and then use `address arithmetic` to traverse the `array`:

- + is used to move forward to a memory location
- is used to move backward to a memory location

Consider the following program:

```
int a[5] = {22, 33, 44, 55, 66};
int *ptr = NULL;
int i;

ptr = a;
for (i = 0; i < 5; i++) {
    printf("%d ", *(ptr + i));
}
```

## C Programming

Wednesday - 18/06/2010

### → Functions in C

- Functions are a vital part of programming for us to accomplish a program's task in a structured way.
- Main() function & printf() function.
- A function:
  - is a block of code that performs a specific task
  - is reusable
  - makes a program easier to test
  - can be modified without changing the calling program's function name (parameters).

### Function Prototype

Within the declaration type and name are included in declaration, the declaration is called a function prototype.

### Function Parameters

A function's parameters are used to receive values required by the function. Values are passed to these parameters via arguments through function call.

### Variable Scope

It refers to the visibility of variable within a program.  
Variables declared within a function are local to that function or global to all of the program.

### > Static Variables

Static variables have a local scope but are not destroyed when a function is exited.  
A static variable is initialized when declared & requires the static state.

### > Recursive Functions

A recursive function is one that calls itself to include while loop, do-while conditions ending the recursive calls. In this case if not facing a problem, the base case is never reached.

### > Arrays in C

- An array is a data structure that stores a collection of related values that can all share the same memory.
- Accessing Array Elements:
  - The content of an 'array' is called elements.
  - with each element accessible by an index no.
  - using loops with arrays

### > Two-dimensional array

A two-dimensional array is an array of arrays from be thought of as a table.

### > Pointers

#### • Using Memory

#### • What is a pointer?

Pointers are very important in C programming because they allows you to directly work with memory locations.  
They are fundamental to arrays, strings, other data structures and algorithms that use type identifiers.

### > Pointers with Expressions

Pointers can be used in expressions just like any variable. Arithmetic operations can be applied to whatever the pointer is pointing to.

### > Making Pointers

- Pointers are especially useful with Arrays
  - It is used to move forward to a memory location
  - is used to move backward to a memory location
- Mem Address arithmetic
  - Address arithmetic can also be thought of as pointer arithmetic. Increases the pointers value by one.
- Pointers & Functions.

### > Functions & Arrays

An array cannot be passed by value to a function however, an array name is a pointer, so just passing an array name to a function is passing a pointer to the array.

### > Functions that Return an Array

A screenshot of a C programming environment. The code editor has a dark background with light-colored text. The code itself is in white. The interface includes tabs for 'Dark' and 'Light' themes, a file selection bar with 'C', and a 'SHARE' button. On the right, there's an 'Output' panel displaying the results of the program execution.

```
c
1 #include <stdio.h>
2
3 int main() {
4     int a, b;
5     float salary = 56.23;
6     char letter = 'Z';
7     a = 8;
8     b = 34;
9     int c = a+b;
10
11    printf("%d \n", c);
12    printf("%f \n", salary);
13    printf("%c \n", letter);
14
15    return 0;
16 }
```

Output

```
42
56.230000
Z
```
